

# Linear equations, matrices and vectors

## Math and modelling for high school, Lecture 1

by Sergei Savin

Fall 2022

# WHAT IS THIS COURSE ABOUT?

In this course we try to do the following:

- Teach you basics of university-level linear algebra, basic introduction to calculus and differential equations and simulation;
- Focus on visual aspect of math: computer graphics, graphs, animation. We do it to use your strength - programming, to help you understand inherently abstract concepts.
- We try to keep the topics coherent and compact, avoiding topics that require deeper algebraic or calculus theory, which forces us to skip many interesting things - which you will surely learn in the university.

The following is a 3 by 3 matrix:

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \quad (1)$$

Examples of 3 by 3 matrices:

$$\mathbf{A} = \begin{bmatrix} 1 & 0 & 0 \\ 2 & 6 & -5 \\ 0 & -3 & 3 \end{bmatrix}, \quad \mathbf{A} = \begin{bmatrix} 10 & 2 & 0 \\ -4 & 5 & 0 \\ -4 & 5 & 2 \end{bmatrix}, \quad \text{etc} \quad (2)$$

The following is a 3-dimensional vector:

$$\mathbf{v} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} \quad (3)$$

Examples 3-dimensional vectors:

$$\mathbf{v} = \begin{bmatrix} 5 \\ 5 \\ 0 \end{bmatrix}, \quad \mathbf{v} = \begin{bmatrix} 4 \\ -3 \\ -1 \end{bmatrix}, \quad \text{etc} \quad (4)$$

Given a vector:  $\mathbf{v} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix}$ , we can find its *norm*:

$$\|\mathbf{v}\| = \sqrt{v_1^2 + v_2^2 + v_3^2} \quad (5)$$

You can think of it as *length* of a vector.

## RECAP: MATRIX-VECTOR PRODUCT

We can find matrix-vector product:

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} a_{11}v_1 + a_{12}v_2 + a_{13}v_3 \\ a_{21}v_1 + a_{22}v_2 + a_{23}v_3 \\ a_{31}v_1 + a_{32}v_2 + a_{33}v_3 \end{bmatrix} \quad (6)$$

An example of a matrix-vector product:

$$\begin{bmatrix} 1 & 0 & 0 \\ 2 & 6 & -5 \\ 0 & -3 & 3 \end{bmatrix} \begin{bmatrix} 1 \\ -2 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ -10 \\ 6 \end{bmatrix} \quad (7)$$

# MATRICES AND VECTORS - RECAP

Matrices don't need to be square. For the matrix-vector product to work, the matrix needs to have as many columns as there are elements in the vector.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} a_{11}v_1 + a_{12}v_2 + a_{13}v_3 \\ a_{21}v_1 + a_{22}v_2 + a_{23}v_3 \end{bmatrix} \quad (8)$$

An example of a matrix-vector product:

$$\begin{bmatrix} 2 & 2 & -1 \\ 0 & 5 & 7 \end{bmatrix} \begin{bmatrix} 0 \\ 2 \\ -2 \end{bmatrix} = \begin{bmatrix} 6 \\ -4 \end{bmatrix} \quad (9)$$

There are many resources on the topic:

- [mathinsight.org/matrix\\_introduction](https://mathinsight.org/matrix_introduction)
- [mathinsight.org/matrix\\_vector\\_multiplication](https://mathinsight.org/matrix_vector_multiplication)
- [mathworld.wolfram.com/L2-Norm.html](https://mathworld.wolfram.com/L2-Norm.html)
- etc.

In Python we can use Numpy package to create matrices and vectors:

- matrix: `A = np.array([[1, -4, 5], [3, 1, -2], [2, -6, -9]])`
- vector: `v = np.array([1, 1, -2])`

Matrix-vector product is done as  $y = A@v$ .

Consider the system of equations:

$$\begin{cases} x_1 + 2x_2 = 10 \\ 2x_1 + 2x_2 = 0 \end{cases} \quad (10)$$

This is the same as:

$$\begin{bmatrix} 1 & 2 \\ 2 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 10 \\ 0 \end{bmatrix} \quad (11)$$

General form for this kind of problem is:

$$\mathbf{Ax} = \mathbf{b} \quad (12)$$

# SYSTEMS OF LINEAR EQUATIONS

In this course we will solve it with

`x = np.linalg.solve(A, b)` functionality of numpy:

```
import numpy as np
A = np.array([[1, 2], [2, 2]])
b = np.array([10, 0])
x = np.linalg.solve(A, b)
print("solution:")
print(x)
print("residual:")
print(A@x - b)
```

# SYSTEMS OF LINEAR EQUATIONS: OTHER DIMENSIONS

Dimensions do not matter, we can deal with equations with 2, 3 and more variables the same way:

$$\begin{cases} x_1 - 4x_2 + 5x_3 = 1 \\ 3x_1 + x_2 - 2x_3 = 1 \\ 2x_1 - 6x_2 - 9x_3 = -2 \end{cases} \quad (13)$$

This is the same as

$$\begin{bmatrix} 1 & -4 & 5 \\ 3 & 1 & -2 \\ 2 & -6 & -9 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ -2 \end{bmatrix} \quad (14)$$

Again, it is  $\mathbf{Ax} = \mathbf{b}$  and we solve it with  
`x = np.linalg.solve(A, b)`.

When we want to note the dimension of a vector, we use the following notation:

$$\mathbf{b} \in \mathbb{R}^n \quad (15)$$

where  $\mathbb{R}$  means space of real numbers and  $n$  is the dimensions.

For matrices it is similar:

$$\mathbf{A} \in \mathbb{R}^{n,n} \quad (16)$$

Why use this strange  $\mathbb{R}$ ? Because later you might see something like  $\mathbf{b} \in \mathbb{C}^n$ , meaning it is a complex vector, or  $\mathbf{b} \in \mathbb{N}^n$  meaning it is a vector of integers.

# DEGENERATE EQS.: TOO MANY VARIABLES

Let us solve a degenerate system of equations:

$$x_1 + 2x_2 = 10 \quad (17)$$

This is the same as

$$\begin{bmatrix} 1 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = 10 \quad (18)$$

General form for this kind of problem is still:

$$\mathbf{Ax} = \mathbf{b} \quad (19)$$

We can solve it with `x, _, _, _ = np.linalg.lstsq(A, b, rcond=None)` functionality of numpy.

## DEGENERATE EQS.: TOO MANY VARIABLES

But what does it even mean to solve  $x_1 + 2x_2 = 10$ ? Let us try to solve it by hand.

We know that  $x_1 = 10 - 2x_2$ . And we can pick any  $x_2$ . For example,  $x_2 = 1$ , then  $x_1 = 10 - 2 = 8$ . Or,  $x_2 = 0$ , then  $x_1 = 10$ . Or,  $x_2 = 4$ , then  $x_1 = 10 - 8 = 2$ . So, all the following  $\mathbf{x}$  are solutions:

$$\mathbf{x} = \begin{bmatrix} 8 \\ 1 \end{bmatrix}, \quad \mathbf{x} = \begin{bmatrix} 10 \\ 0 \end{bmatrix}, \quad \mathbf{x} = \begin{bmatrix} 2 \\ 4 \end{bmatrix}. \quad (20)$$

The numpy function `lstsq` will pick *smallest norm solution* out of all possible ones. In this case, it is,  $\mathbf{x} = \begin{bmatrix} 2 \\ 4 \end{bmatrix}$ .

# TOO MANY EQUATIONS

Let us solve a degenerate system of equations:

$$\begin{cases} x_1 + 2x_2 = 2 \\ 3x_1 - 5x_2 = 0 \\ 2x_1 - 4x_2 = 5 \end{cases} \quad (21)$$

This is the same as

$$\begin{bmatrix} 1 & 2 \\ 3 & -5 \\ 2 & -4 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 2 \\ 0 \\ 5 \end{bmatrix} \quad (22)$$

General form for this kind of problem is still:

$$\mathbf{Ax} = \mathbf{b} \quad (23)$$

Again, we just use `x, _, _, _ = np.linalg.lstsq(A, b, rcond=None)`.

# DEGENERATE SYSTEM OF EQUATIONS

```
0 A = np.array([[1, 2], [3, -5], [2, -4]])  
  b = np.array([[2], [0], [5]])  
2 x, -, -, - = np.linalg.lstsq(A, b, rcond=None)  
  e = A@x - b;  
4 print("solution: " + str(x.T));  
  print("residual: " + str(e.T));
```

The output for this example is:

```
0 solution: [[1.07936508  0.14814815]]  
  residual: [[-0.62433862   2.4973545  -3.43386243]]
```

Notice the residual is **not zero**. Note that the function `lstsq` will pick solution with *smallest-norm residual*.

# DEGENERATE SQUARE SYSTEM

The following system is square (same number of variable and equations) but you still cannot solve it normally:

$$\begin{cases} x_1 - 2x_2 = 0 \\ 3x_1 - 6x_2 = 2 \end{cases} \quad (24)$$

This is the same as:

$$\begin{bmatrix} 1 & -2 \\ 3 & -6 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 2 \end{bmatrix} \quad (25)$$

And it does not have a zero-residual solution.

# HOW DO YOU TELL IF A SYSTEM CAN BE SOLVED?

The test is - to find if the matrix *determinant* is not zero. For 2 by 2 matrices, the determinant is found as follows:

$$\mathbf{A} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \quad (26)$$

$$\det(\mathbf{A}) = ad - bc \quad (27)$$

For anything other than 2 by 2 we find determinant as `d = np.linalg.det(A)` functionality of numpy.

If a matrix has 0 determinant we call it *degenerate*. If the matrix has non-zero determinant, we call it *full-rank*.

Given a few vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n \in \mathbb{R}^n$ , their linear combination is defined as:

$$\mathbf{w} = \alpha_1 \mathbf{v}_1 + \alpha_2 \mathbf{v}_2 + \dots + \alpha_n \mathbf{v}_n \quad (28)$$

where  $\alpha_i \in \mathbb{R}$  are linear coefficients.

Example: Given  $\mathbf{v}_1$  and  $\mathbf{v}_2$ :

$$\mathbf{v}_1 = \begin{bmatrix} 1 \\ 3 \end{bmatrix}, \quad \mathbf{v}_2 = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad (29)$$

Then examples of their linear combinations are:

$$\mathbf{w} = 2\mathbf{v}_1 - \mathbf{v}_2 = 2 \begin{bmatrix} 1 \\ 3 \end{bmatrix} - \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 2 \\ 5 \end{bmatrix} \quad (30)$$

$$\mathbf{w} = -3\mathbf{v}_1 + 2\mathbf{v}_2 = -3 \begin{bmatrix} 1 \\ 3 \end{bmatrix} + 2 \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} -3 \\ -7 \end{bmatrix} \quad (31)$$

$$\mathbf{w} = 5\mathbf{v}_2 = 5 \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 5 \end{bmatrix} \quad (32)$$

If a set of vectors contain none that is a linear combination of the others - we call them *linearly independant*.

If one of your matrix's columns is a linear combination of the other - it will be degenerate. Lets look for an example.  
Consider the matrix:

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \quad (33)$$

Its columns are  $\mathbf{a}_1$  and  $\mathbf{a}_2$ :

$$\mathbf{a}_1 = \begin{bmatrix} a_{11} \\ a_{21} \end{bmatrix}, \quad \mathbf{a}_2 = \begin{bmatrix} a_{12} \\ a_{22} \end{bmatrix} \quad (34)$$

If, for instance,  $\mathbf{a}_2 = 2\mathbf{a}_1$ , the matrix  $\mathbf{A}$  will be degenerate.

An example of a matrix with linearly dependent columns:

$$\mathbf{a}_1 = \begin{bmatrix} 2 \\ -3 \end{bmatrix}, \quad \mathbf{a}_2 = -\mathbf{a}_1 = \begin{bmatrix} -2 \\ 3 \end{bmatrix} \quad (35)$$

Then matrix  $\mathbf{A} = \begin{bmatrix} 2 & -2 \\ -3 & 3 \end{bmatrix}$  is degenerate, and  $\det(\mathbf{A}) = 0$ .

Meaning, you can't solve a system like this one:

$$\begin{cases} 2x_1 - 2x_2 = 1 \\ -3x_1 + 3x_2 = 0 \end{cases} \quad (36)$$

Really though? Let us check.  $-3x_1 + 3x_2 = 0$ , therefore  $x_1 = x_2$ , and since  $2x_1 - 2x_2 = 1$  we get  $2x_1 - 2x_1 = 1$  and so  $0 = 1$ , which is clearly incorrect.
